Transcript:

Hi, I'm Rajavel. My project is Diagnostic Lab portal. Actually, the website is mainly developed for managing the lab works. When the hospital needs to do test for a patient, they will send the request to the laboratory. In our website, lab staff can see those request and check whether all details are correct. After the checking, they will process the test and enter the result. Once the When the result is ready, our system will create a CSV file and send back to the hospital through the Dropbox API. And about the usage of my website is the first laboratory staff will log When they will go in to the website, they will see the incoming test request and check the patient details and the information. After checking the process, they can process the test and enter the result in the website, like in the CSV form, or something, Json. They can also see the request, which are the pending request and which are completed. Apart from this, the hospital staff can also involved in this process. They send their a test request and receive completed test results. Apart from the activities, they can help the hospital laboratory to work in a better Now, coming to the technical side, I have used several technologies for front-end and back-end.For front-end, I use HTML, CSS, JavaScript to design the website and make it for users interactivity. For the back-end, I use the Python with Flask. It handles the login process, test request, and result management. For CSV processing, I use the Pandas. For storing, I use the SQL light database. It stores the laboratory user's test request and test results. Finally, I use the Dropbox API to exchange the files between the hospital and laboratory portal. The request files are downloaded from the Request folder, and after processing the request, the result files are uploaded to the Request folder. Folder. So these are the technologies used in my website. Thank you.
